Adapter Pattern

The **Adapter Pattern** is a design pattern that lets two systems or components that weren't designed to work together communicate with each other by creating a bridge between them.

Problem Statement

Imagine you're building an **e-commerce website** (like Flipkart or Amazon) that sends email notifications to customers (order confirmations, shipping updates, etc.).

Right now, you're using your own custom email system called ***EmailNotificationService***. Everything works fine!

But now you want to switch to a popular third-party email service like ***SendGrid*** (which is faster, more reliable, and handles spam better).

The Problem: Your existing code expects one interface, but SendGrid has a completely different interface. They don't match!
